

Radiative cooling approximations and the beginning of planet formation

ALISON K. YOUNG, MAGGIE CELESTE, RICHARD BOOTH, KEN RICE,
DIMITRIS STAMATELLOS, ETHAN CARTER

But first... who am I?

- Star formation, first hydrostatic cores, chemistry, synthetic observations...

But first... who am I?

- sink feedback + chemistry

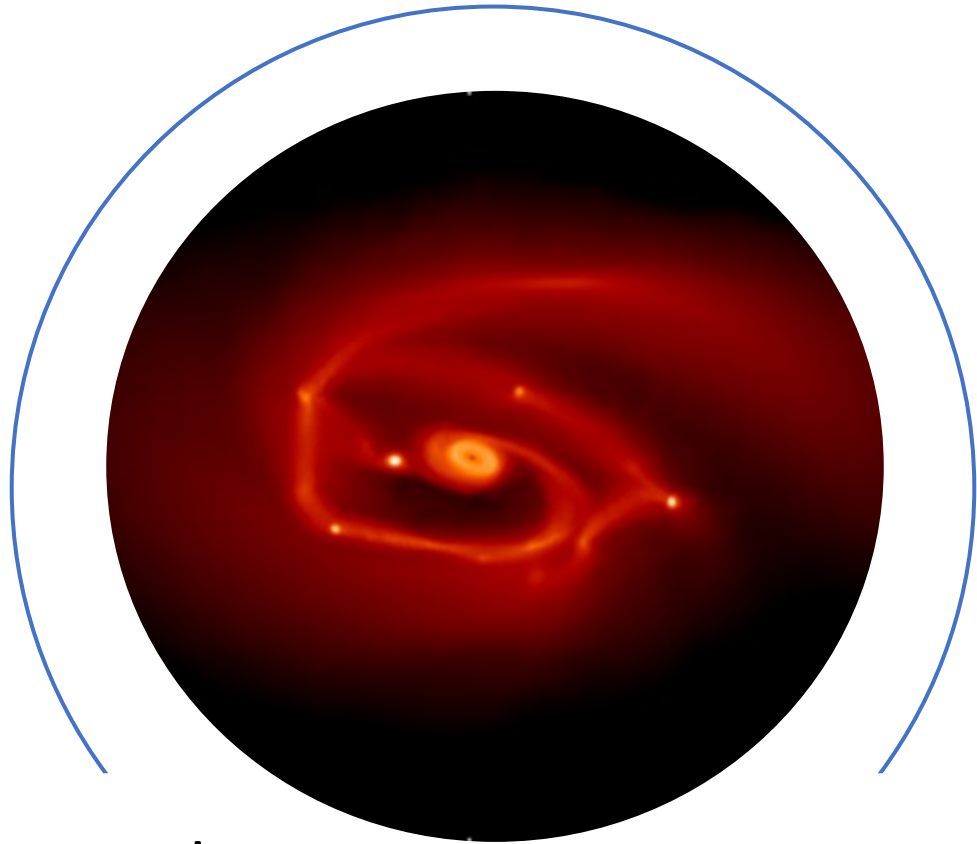

But first... who am I?

- warps & breaks in protoplanetary discs & chemistry too...

Young+ 2021

Radiative cooling approximations and the beginning of planet formation

ALISON K. YOUNG, MAGGIE CELESTE, RICHARD BOOTH, KEN RICE,
DIMITRIS STAMATELLOS, ETHAN CARTER

The problem:

IRS 63 – no more than 500,000 years old

Planets form early and quickly
What does this mean?

Segura-Cox+ 2020

Growing planetesimals quickly

- need to form planetesimals within few 100 kyr
- young discs are more massive and subject to gravitational instability
- how does grain growth occur in turbulent discs?

Modelling young discs - challenges

- more massive and subject to gravitational instability
- internal heating
- stability very sensitive to cooling rate
- accretion streamers
- dynamical interactions with neighbour stars
- What are the “initial conditions” for young discs?

Modelling cooling in massive discs

- Gravitational instability is key source of heating and viscosity (turbulence)
- Cooling rate governs whether disc fragments etc.
- Full radiative transfer is prohibitively expensive (except if you're Sahl)
- We need an effective approximate treatment

Current options: beta cooling

- $t_c = \beta / \Omega$ Gammie (2001)
- cooling time parameterised as a function of orbital period (radius)
- can't account for disc structures
- doesn't tell us much about the physics

Current options: polytropic cooling v1

Stamatellos+ (2007)

mass- weighted average of $\Sigma_i(\xi)$ over all possible dimensionless radii, ξ

pseudo-mean column-density

$$\bar{\Sigma}_i = \zeta_n \left[\frac{-\psi_i \rho_i}{4\pi G} \right]^{1/2},$$

A constant

We already calculate the potential 😊

pseudo-mean optical depth

$$\bar{\tau}_i = \bar{\Sigma}_i \bar{K}_i.$$

Current options: polytropic cooling v1

Stamatellos+ (2007)

radiative cooling
rate

$$\left. \frac{du_i}{dt} \right|_{\text{rad}} = \frac{4\sigma \left(T_0^4(\mathbf{r}_i) - T_i^4 \right)}{\underbrace{\bar{\Sigma}^2 \bar{\kappa}_i(\rho_i, T_i) + \kappa_i^{-1}(\rho_i, T_i)},}$$

Background
temperature

Can set this to ISRF +
stellar irradiation

pseudo-mean
optical depth

Assume that gas cools/heats
towards an equilibrium
temperature.

Current options: polytropic cooling v1

Assume that gas cools/heats towards an equilibrium temperature.

$$\left. \frac{du_i}{dt} \right|_{\text{rad}} = \frac{4\sigma (T_0^4(\mathbf{r}_i) - T_i^4)}{\bar{\Sigma}^2 \bar{\kappa}_i(\rho_i, T_i) + \kappa_i^{-1}(\rho_i, T_i)},$$

$$\left. \frac{du_i}{dt} \right|_{\text{hydro}} + \left. \frac{du_i}{dt} \right|_{\text{rad}} = 0,$$

$$u_{\text{eq},i} = u(\bar{T}_{\text{eq},i}, \rho_i).$$

Substitute T_{eq} for T_i
Assume heating/cooling
balance to find
equilibrium temperature

This gives an equilibrium energy

$$t_{\text{therm},i} = (u_{\text{eq},i} - u_i) \left[\left. \frac{du_i}{dt} \right|_{\text{hydro}} + \left. \frac{du_i}{dt} \right|_{\text{rad}} \right]^{-1}.$$

with thermal timescale

Stamatellos+ (2007)

Current options: polytropic cooling v1

$$t_{\text{therm},i} = (u_{\text{eq},i} - u_i) \left[\frac{du_i}{dt} \Big|_{\text{hydro}} + \frac{du_i}{dt} \Big|_{\text{rad}} \right]^{-1}.$$

Cooling (heating) rate is then:

$$\frac{du_i}{dt} \Big|_{\text{cool}} = \frac{1}{\delta t} \left[u_i \exp\left(\frac{-\delta t}{t_{\text{therm},i}}\right) + u_{\text{eq},i} \exp\left(\frac{-\delta t}{t_{\text{therm},i}}\right) \right] + \frac{du_i}{dt} \Big|_{\text{hydro}}. \quad (12)$$

Current options: polytropic cooling v1

		Pros	Cons

New: "Modified Lombardi" Method

Can we do even better?

Yes!

In a disc geometry, the mid-plane density, scale-height and column density are related by $\Sigma = \sqrt{\frac{\pi}{2}} H_* \Sigma_0$ where $H_* = c_s / \Omega$

But if the disc's self-gravity compresses the gas further:

$$H_0 = \frac{H_* t}{\sqrt{1 + 1/(t Q_{3D})}} \quad t = \sqrt{\pi/2}$$

From vertical hydrostatic equilibrium and substituting

$$Q_{3D} = \Omega^2 / 4\pi G \rho(0)$$

$$H_{ML} = \sqrt{\frac{1}{H_L^{-2} + H_0^{-2}}}$$

Still minimal extra cost 😊

New: "Modified Lombardi" Method

Alison Young

$$H_0 = \frac{H_* t}{\sqrt{1 + 1/(tQ_{3D})}}$$

$$t = \sqrt{\pi/2}$$

$$H_{ML} = \sqrt{\frac{1}{H_L^{-2} + H_0^{-2}}}$$

Still minimal extra cost 😊

Does it work?

★ Low mass disc

High mass disc 1

Does it work?

High mass disc 2

New methods demonstrate far better estimates of column density and scale height.

Higher mass disc 2

Does it work?

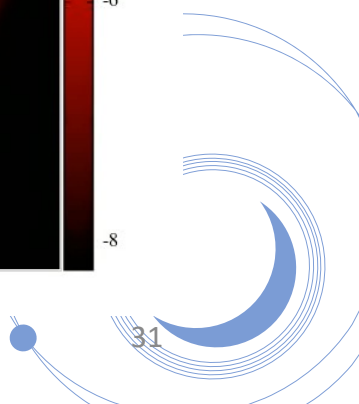

New methods demonstrate far better estimates of column density and scale height.

What next?

- submit paper!
- fragmentation in young discs
- synthetic observations of very young discs

+ Tom Bending (Exeter)

What next?

- Dust transport in 'realistic' young discs
- Merge with main repo ...?!

Projected dust-to-gas mass ratio in a quasi-stable disc extracted from the Bate (2012) simulation. 50 cm dust grains were injected into the gaseous disc with an initial dust fraction of 0.01 and allowed to evolve taking drag and self-gravity into account.

Summary

- When cooling is important – use these new methods ;)
- radiative cooling need not be expensive
- Can couple with flux-limited diffusion for radiative transfer approximation
- Can prescribe a spatially varying background temperature for e.g. stellar heating.

Thanks to Adam Koval
for making many
figures!
